

## Basics I: Arithmetic

Topic	Interpretation
<p><b>The Real Numbers</b></p> <p>N:Natural (counting) Numbers W:Whole Numbers Z:Integers Q:Rational Numbers I:Irrational numbers</p> <p><math>N \subseteq Z \subseteq Q</math> <math>R = Q \cup I</math></p>	<p>1,2,3,4,..... 0,1,2,3,4,..... .....,-3,-2,-1,0,1,2,3,..... All numbers of the form <math>a/b</math>, where a and b are integers with <math>b \neq 0</math> e.g. <math>3/2</math>, <math>-2/7</math>, <math>5 = 5/1</math> Real numbers that are not Rational e.g. <math>\pi</math> All the above numbers are <i>real</i> numbers.</p>
<p><b>Order of operations</b></p> <p>Follow the following order as they occur working from left to right:</p> <ol style="list-style-type: none"> <li>1.Parentheses &amp; square brackets</li> <li>2.Powers</li> <li>3.Multiplication or division</li> <li>4.Addition or subtraction</li> </ol>	$\frac{2(-2-5)^2 + 4(5)}{-3+4} = \frac{2(-7)^2 + 20}{1}$ $= \frac{2(49)^2 + 20}{1} = 2(49)+20 = 98+20 = 118$ $\frac{-11 - (-12) - 4 \times 5}{4(-2) - (-6)(-5)} = \frac{-11 + 12 - 20}{-8 - (+30)} = \frac{-19}{-38}$ $= \frac{19}{38} = \frac{1}{2} = 0.5$
<p><b>Absolute Value</b></p> $ x  = \begin{cases} -x & \text{if } x < 0 \\ +x & \text{if } x \geq 0 \end{cases}$ <p><math> x  \geq 0</math> for every x <math> x - y  \neq  x  -  y </math> <math> x + y  =  x  +  y </math> for x,y having the same sign.</p>	<p><math> -5  = 5</math> ; <math> 5  = 5</math></p> <p><math> 3 - 7  =  -4  = 4</math> <math> 3  -  7  = 3 - 7 = -4</math> <math> 5+4  =  9  = 9</math> <math> 5  +  4  = 5 + 4 = 9</math></p>
<p><b>Fractions Addition</b></p> $\frac{a}{b} + \frac{c}{d} = \frac{ad + bc}{bd}$	$\frac{3}{7} - \frac{5}{8} = \frac{8 \times 3 - 7 \times 5}{56} = \frac{24 - 35}{56} = \frac{-11}{56}$

<p><b>Square roots</b>            There are two numbers whose square is 25 : -5 and 5  <math>(-5)^2 = -5 \times -5 = 25</math>  <math>5^2 = 5 \times 5 = 25</math>            The <i>positive</i> one, 5, is called the square root of 25.  <math>\sqrt{x} \geq 0</math> for every real number <math>x</math>            For <math>\sqrt{x}</math> to exist , <math>x \geq 0</math>  <math>(\sqrt{x})^2 = \sqrt{x} \times \sqrt{x} = x</math>  <math>\sqrt{x+y} \neq \sqrt{x} + \sqrt{y}</math>  <math>\sqrt{x} \times \sqrt{y} = \sqrt{xy}</math>  <math>\frac{\sqrt{x}}{\sqrt{y}} = \sqrt{\frac{x}{y}}</math></p>	<p><math>\sqrt{49} = 7</math> since <math>7^2 = 49</math>  <math>\sqrt{-25}</math> does not exist.  <math>\sqrt{16+9} = \sqrt{25} = 5</math>  <math>\sqrt{16} + \sqrt{9} = 4 + 3 = 7</math>  <math>4\sqrt{5} \times 7\sqrt{3} = 28\sqrt{15}</math>  <math>\frac{\sqrt{2}}{\sqrt{3}} = \sqrt{\frac{2}{3}}</math>  <math>\sqrt{2} \times \sqrt{2} = 2</math>  <math>7\sqrt{2} \times 3\sqrt{2} = 21 \times 2 = 42</math>  <math>\frac{5}{\sqrt{3}} = \frac{5}{\sqrt{3}} \times \frac{\sqrt{3}}{\sqrt{3}} = \frac{5\sqrt{3}}{3}</math>            Estimate <math>\sqrt{73}</math> since <math>8^2 = 64</math> and <math>9^2 = 81</math>  <math>\sqrt{73}</math> must be between 8 and 9.</p>
<p><b>Exponents</b>  <math>x^m \times x^n = x^{m+n}</math>  <math>\frac{x^m}{x^n} = x^{m-n}</math>  <math>(x^m)^n = x^{mn}</math>  <math>\frac{1}{x^m} = x^{-m}</math>  <math>\sqrt{x} = x^{\frac{1}{2}}</math>  <math>\sqrt[n]{x^m} = x^{\frac{m}{n}}</math></p>	<p><math>2x^3 \times 5x^4 = 10x^7</math>  <math>\frac{-12x^7}{6x^5} = -2x^2</math>  <math>(2x^2)^3 = 2^3 x^6 = 8x^6</math>  <math>\frac{1}{x^3} = x^{-3}</math>  <math>\sqrt{25x^4} = 5x^{\frac{4}{2}} = 5x^2</math>  <math>\sqrt[5]{x^3} = x^{\frac{3}{5}}</math></p>
<p><b>Polynomials</b>            In the expression <math>2x^3</math> , <math>x</math> is called a <i>variable</i> because it can assume any number of different values.            2 is called the coefficient.            The highest power that appears in a polynomial is the degree of the polynomial.  <math>2x - 5x^3 + 7x^2</math> is of degree 3</p>	<p>Like terms of a polynomial can be added or subtracted, unlike terms can not.  <math>9x^5 - 15x^5 = -6x^5</math>  <math>3x + 4x^2 = 3x + 4x^2</math>            Multiplication :    <math>(2x - 1)(3x + 5)</math>  <math>= (2x)(3x) + (2x)(5) - (1)(3x) - (1)(5)</math>  <math>= 6x^2 + 10x - 3x - 5 = 6x^2 + 7x - 5</math></p>

<p><b>Factoring</b> The number 10 can be written as <math>5 \times 2</math>, <math>1 \times 10</math>,.... The numbers in each product are called <i>factors</i>, the process of writing 10 as a product of factors is called <i>factoring</i>.</p> <p><b>Difference of two squares</b> <math>(a-b)(a+b) = a^2 - b^2</math></p> <p><math>a^2 + b^2</math> can not be factored in real numbers and is always positive; <math>x^2 + 5 &gt; 0</math> for every <math>x</math> real number.</p> <p><b>Difference of two cubes</b> <math>a^3 - b^3 = (a-b)(a^2 + ab + b^2)</math></p> <p><b>Sum of two cubes</b> <math>a^3 + b^3 = (a+b)(a^2 - ab + b^2)</math></p> <p><b>Perfect Squares</b> <math>(a + b)^2 = (a+b)(a+b)</math> <math>= a^2 + 2ab + b^2</math> <math>(a - b)^2 = (a - b)(a - b)</math> <math>= a^2 - 2ab + b^2</math></p> <p><b>Perfect Cubes</b> <math>(a+b)^3 = a^3 + 3a^2b + 3ab^2 + b^3</math> <math>(a - b)^3 = a^3 - 3a^2b + 3ab^2 - b^3</math></p> <p><b>Factoring Trinomial</b> A trinomial is a polynomial with three terms. Our concern here is those of degree 2 : <math>x^2 + bx + c</math> ;when it is possible, can be factored into two factors <math>(x + m)(x+n)</math> Look for the factors of the constant term <math>c</math> whose sum (or difference) is <math>b</math> ; being factors of <math>c</math> ,their product is <math>c</math> . <math>x^2 + 5x + 4</math> the factors of 4 whose sum is 5 are 1 and 4 <math>x^2 + 5x + 4 = (x+1)(x+4)</math></p>	<p><u>Example1</u>: factor <math>12x - 18y</math> Both <math>12x</math> and <math>18y</math> are divisible by 6 : <math>6(2x) - 6(3y) = 6(2x - 3y)</math></p> <p><u>Example2</u>: <math>8x^3 - 9x^2 + 15x</math> Each of these terms is divisible by <math>x</math> : <math>x(8x^2) + x(-9x) + x(15) = x(8x^2 - 9x + 15)</math></p> <p><u>Example3</u>: <math>5(4x-3)^3 - 2(4x-3)^2</math> <math>(4x-3)^2</math> is the common factor : <math>(4x-3)^2 [ 5(4x-3) - 2 ] = (4x-3)^2(20x-17)</math></p> <p><u>Example4</u>: <math>x^2 - 16 = x^2 - 4^2 = (x-4)(x+4)</math></p> <p><u>Example5</u>: <math>81x^4 - 16 = (9x^2)^2 - (2^2)^2</math> <math>= (9x^2 - 4)(9x^2 + 4)</math> <math>= (3x-2)(3x+2)(9x^2 + 4)</math></p> <p><u>Example6</u>: <math>x^3 - 8 = x^3 - 2^3</math> <math>= (x-2)(x^2 + 2x + 4)</math></p> <p><u>Example7</u>: <math>y^3 + 125 = y^3 + 5^3</math> <math>= (y+5)(y^2 - 5y + 25)</math></p> <p><u>Example8</u>: <math>(2x - 7)^2 = (2x)^2 - 2(2x)(7) + 7^2</math> <math>= 4x^2 - 28x + 49</math></p> <p><u>Example9</u>: <math>(q - 2)^3</math> <math>= q^3 - 3(q^2)(2) + 3q(2^2) - 2^3</math> <math>= q^3 - 6q^2 + 12q - 8</math></p> <p><u>Example9</u>: Factor <math>x^2 - x - 6</math> The factors of 6 whose sum or difference is <math>-1</math> are 2 and <math>-3</math> (notice their product is <math>-6</math>) : <math>(x - 3)(x+2)</math></p> <p><u>Example10</u>: Factor <math>4y^2 - 11y + 6</math> Here the factors should look like: <math>(2y \quad)(2y \quad)</math> or <math>(4y \quad)(y \quad)</math> We do it by trial :we need 6 at the end ,i.e. <math>(-1)(-6)</math> , <math>(1)(6)</math> , <math>(2)(3)</math> or <math>(-2)(-3)</math> <math>(2y - 1)(2y - 6) = 4y^2 - 14y + 6</math> NO <math>(2y - 2)(2y - 3) = 4y^2 - 14y + 6</math> NO <math>(4y - 3)(y - 2) = 4y^2 - 11y + 6</math> YES</p>
