

## BasicsIII: Graphing

Study Guide pp 17-22; Anthony & Biggs pp 17-19

Topic	Interpretation															
<p><b>Graphs</b> The graph of an equation in two variables is the set of points in the plane whose coordinates are solutions of the equation. <u>Example:</u> Sketch the graph of <math>y = 2x + 3</math> Construct a table of y-values for a reasonable number of x-values:</p> <table border="1" data-bbox="232 1003 621 1245"> <thead> <tr> <th>x</th> <th><math>y = 2x+1</math></th> <th>(x,y)</th> </tr> </thead> <tbody> <tr> <td>-1</td> <td>-1</td> <td>(-1,-1)</td> </tr> <tr> <td>0</td> <td>1</td> <td>(0,1)</td> </tr> <tr> <td>1</td> <td>3</td> <td>(1,3)</td> </tr> <tr> <td>2</td> <td>5</td> <td>(2,5)</td> </tr> </tbody> </table>	x	$y = 2x+1$	(x,y)	-1	-1	(-1,-1)	0	1	(0,1)	1	3	(1,3)	2	5	(2,5)	 <p>x-intercept: <math>\cap</math> x-axis: <math>y = 0</math>  <math>2x + 1 = 0 \Rightarrow x = \frac{-1}{2} ; (\frac{-1}{2}, 0)</math></p> <p>y-intercept: <math>\cap</math> y-axis : <math>x = 0</math>  <math>y = 2(0) + 1 = +1 ; (0, 1)</math></p>
x	$y = 2x+1$	(x,y)														
-1	-1	(-1,-1)														
0	1	(0,1)														
1	3	(1,3)														
2	5	(2,5)														
<p><b>Quadratic Curves</b> <math>Y = ax^2 + bx + c</math> <math>x = \frac{-b}{2a}</math> is the axis of symmetry and the x-value of the vertex <u>Example:</u> the vertex of the Parabola : <math>Y = 2x^2 - 4x + 5</math> <math>a = 2</math> , <math>b = -4</math> and <math>c = 5</math> <math>x = \frac{-b}{2a} = \frac{4}{4} = 1</math> Substitute this in Y : <math>Y = 2(1)^2 - 4(1) + 5 = 3</math> the vertex : <math>(1, 3)</math></p>	 <p><math>a &gt; 0</math>                      <math>a &lt; 0</math></p>															

Example:

Sketch the graph of  
 $y = 2x^2 + 2x - 4$   
 $a=2, b=2, c=-4$

1.) Vertex:  $x = \frac{-b}{2a} =$

$\frac{-2}{4} = \frac{-1}{2}$  Substitute this in  $y$  :

$y = \frac{-9}{2} \Rightarrow V\left(\frac{-1}{2}, \frac{-9}{2}\right)$

2.) x-intercept :  $y = 0$

$2x^2 + 2x - 4 = 0$

$(2x - 2)(x + 2) = 0$

$x = 1$  or  $x = -2$

$(1, 0) ; (-2, 0)$

3.) y-intercept :  $x = 0$

$y = 2(0)^2 + 2(0) - 4 = -4$

$(0, -4)$

In case where there are no x-intercepts, construct a table of y-values as in the first example.

**y-axis symmetry**

**Intersection points**

Set  $y = y$  and solve for  $x$ .

Example :

Let  $f(x) = 4x^2 - 8x - 1$  and

$g(x) = -4x^2 - 2x + 4$

Determine the positive value of  $x$  at which these two graphs intersect.

(LSE 2004)

$4x^2 - 8x - 1 = -4x^2 - 2x + 4$

$8x^2 - 6x - 5 = 0$

$a = 8, b = -6, c = -5$

$$x = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a} = \frac{6 \pm \sqrt{36 + 160}}{16}$$

$$x = \frac{6 \pm \sqrt{196}}{16} = \frac{6 \pm 14}{16}$$

Either  $x = \frac{6 - 14}{16} = \frac{-8}{16} = \frac{-1}{2}$

Or  $x = \frac{6 + 14}{16} = \frac{20}{16} = \frac{5}{4} > 0$  which is

the required.
